Internal Network Penetration & Vulnerability Assessment

-Daniel Sheehan

Introduction

In this report I will be performing an audit on a remote machine and looking for vulnerabilities using NMAP to scan ports, find outdated software and searching if there are any exploits online on exploit databases. I will be identifying outdated software, analysing each service's purpose and how vulnerable it might leave the machine. I will then be using penetration software such as Armitage to exploit the outdated software and check its effectiveness. Finally using a topology provided I will set up static routing and an access control list to restrict and allow access on specified networks.

<u>Scan of Remote Machine (NMAP)</u>

```
I will begin by running an NMAP
                                                           –(kadmin⊛kali)-[~]
scan on the IP Address
192.16.63.41
                                                          -$ nmap -sV 172.16.63.41
To do this run the following
                                                      Starting Nmap 7.94 ( https://nmap.org ) at 2024-02-23 12:27 GMT
command:
Nmap -sV 172.16.63.41
                                                      Nmap scan report for 172.16.63.41
Host is up (0.023s latency).
Not shown: 977 closed tcp ports (conn-refused)
PORT STATE SERVICE VERSION
The reason for running this scan
                                                                                             VERSION

On port 22 I can see there is an
open ssh server.
Here I can see that the version
of SSH is OpenSSH 4.7 on a
Ubuntu machine. I checked the
OpenSSH website to check the
```

current version and found that OpenSSH is currently on version 9.6, this tells us that this server is running an extremely outdated version of the software leaving their machine vulnerable to attacks.

According to their website
OpenSSH 4.7 was released in
September 2007 meaning the
version running on this machine
is 16 years old. This is extremely
unsafe and should be updated
urgently as this provides
attackers with an easy point of
access. I recommend updating
to the current version

An open ssh server on port 22 can leave a machine vulnerable because it gives attackers a potential entry point allowing them to access the system. SSH stands for secure shell and is used to secure remote access and control over a network, if it is left open and isn't updated to the current version it can expose the system to brute force attacks and other exploits, If the unauthorized user gains entry then they have a free run at all data stored on the network.

Upon researching this version of OpenSSH online I found a variety of sites such as exploitdb and cve-details where exploits have been shared in relation to this version of OpenSSH (4.7)

As an example hereⁱ I found a post on cvedetails stating that versions of OpenSSH before 9.3 including this one have an untrustworthy search path which could allow hackers to remotely execute their own code on the remote machine

OpenSSH 4.7 was released on 2007-09-05. It is available from the mirrors listed at https://www.openssh.com/.

OpenSSH Release Notes

OpenSSH 9.6/9.6p1 (2023-12-18)

OpenSSH 9.6 was released on 2023-12-18. It is available from the mirrors listed at https://www.openssh.com/.
OpenSSH is a 100% complete SSH protocol 2.0 implementation and includes sftp client and server support.

This is ranked as a critical exploit meaning it could have severe repercussions it may be best to install the current version to prevent this from happening.

The next thing that I noticed about this machine is that it had an Apache server running on port 80. Apache is an open source HTTP software used to accept HTTP requests allowing users to visit websites.

This Apache server is running on a Ubuntu Machine and the app version is Apache 2.2.8, Upon researching this Apache is currently on version 2.4.58 meaning that the software is outdated and could potentially be leaving the remote machine vulnerable to attack. An outdated Apache http server on port 80 could leave the machine vulnerable as it may contain bugs and security risks that have been patched in newer and more recent versions. Hackers could exploit these oversights to steal unencrypted data or even use the machine as a way into the server hosting it and attack on a larger scale, they could also potentially run denial of service attacks to block legitimate requests.

The fact that the website is running through HTTP and not HTTPS is also a massive security risk as the site data such as usernames and passwords are being stored as plain text making it readable to anybody who has the ability to intercept the communication and follow the stream, If the site was HTTPS this would not be an issue as all stored data is encrypted. I would recommend

80/tcp open http Apache httpd 2.2.8 ((Ubuntu) DAV/2)

changing to HTTPS when handling data as it is more secure and poses less risk.

I would also recommend updating Apache to it's current version of 2.4.58 in order to patch any bugs and eliminate a variety of security risks.

Upon researching any possible vulnerabilities relating to Apache 2.2.8 I found a postⁱⁱ stating that any version of Apache before 2.4.53 including this one was at risk of denial of service as there was no default limit on the possible input size when a particular lua script was used essentially meaning the server could be pushed beyond a limit it could handle.

This means that an attacker with knowledge of this could send a large amount of data to the server in order to overwhelm it, push it past its limit and cause it to stop responding. All of this can be prevented by simply updating the software.

Apache 2.2.8 released in 2005 meaning this software is 18 years out of date and should be top of our list of priorities in terms of updating outdated software.

On port 3306 I noticed that there was an instance of MySQL running on our remote ubuntu machine connected to the server. SQL is a programming language used for managing databases. The version of MySQL running on this machine is 5.0.51a-3, the current version of MySQL is 8.3.0 meaning that

Vulnerability Details: CVE-2022-29404

In Apache HTTP Server 2.4.53 and earlier, a malicious request to a lua script that calls r:parsebody(0) may cause a denial of service due to no default limit on possible input size.

Threat overview for CVE-2022-29404

3306/tcp open mysql

MySQL 5.0.51a-3ubuntu5

Vulnerability Details: CVE-2023-38408

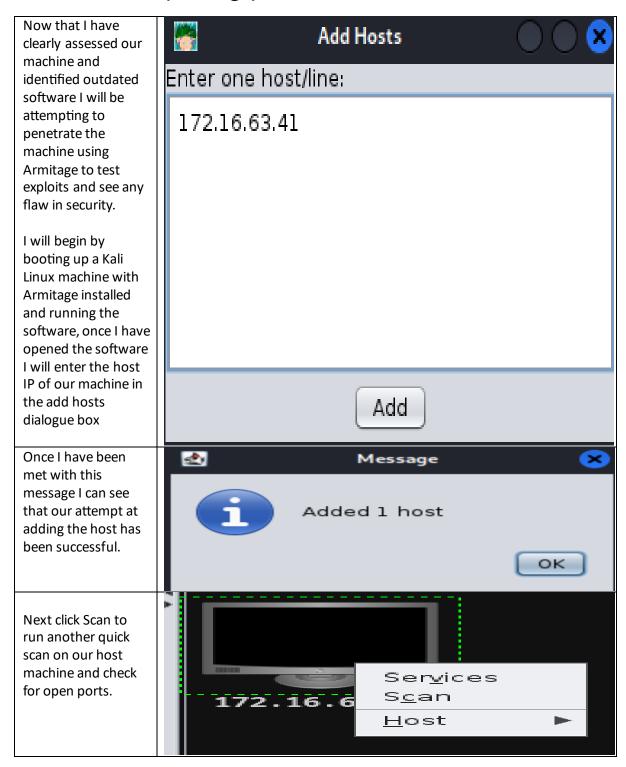

The PKCS#11 feature in ssh-agent in OpenSSH before 9.3p2 has an insufficiently trustworthy search path, leading to remote code execution if an agent is forwarded to an attacker-controlled system. (Code in /usr/lib is not necessarily safe for loading into ssh-agent.) NOTE: this issue exists because of an incomplete fix for CVE-2016-10009.

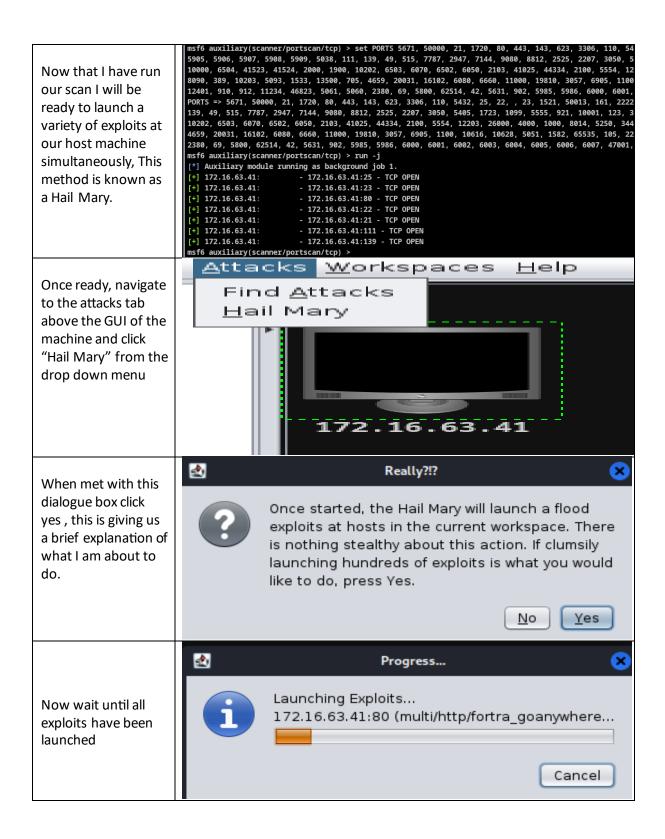

the version on our remote machine is extremely out of date. One major risk of an outdated version of MySQL is that it could allow attackers to execute malicious code that could allow unauthorized access and loss of data.

After researching exploits online for this version of MySQLI found this postⁱⁱⁱ that stated any versions of MySQL before version 9.3p2 had untrustworthy search paths that could allow an attacker to remotely inject code and harm the system. I would suggest updating OpenSSH to the current version immediately in order to prevent this from happening. OpenSSH version 5.0 51a came out in January 2008 meaning it is 16 years out of date which is a massive concern in regard to our audit.

Right click on the Red Host machine Attack image and select Login shell 1, from the Shell 1 drop down menu Interact select interact. Services 172.10 Upload... Scan Pass Session This should open a <u>H</u>ost \blacktriangleright Post Modules CLI shell Disconnect In the shell I have \$ cd /home opened I will first \$ 1s enter the home dav directory by typing: dvwa cd/home index.php I will then check mutillidae what is contained in phpMyAdmin the home directory by typing list phpinfo.php function: test ls tikiwiki tikiwiki-old when I type Is /home I can see a twiki folder named \$ 1s /home msfadmin which ftp would seem important and pique msfadmin an attacker's interest service I will access this folder to check it's user contents by typing: \$ ls /home/msfadmin Is /home/msfadmin hello secretDirectory I have found a directory named vulnerable secretDirectory, \$ ls /home/msfadmin/secretDirectory finally I will list it's contents to see what passwords.txt it may contain: superSecretDirectory \$ cat /home/msfadmin/secretDirectory/passwords.txt /home/msfadmin/s Password01 ecretDirectory 4BlindMice

In this secret \$ ls /home/msfadmin/secretDirectory directory I have found a file named passwords.txt Our searching seems to have paid off and I will view the contents by typing: Cat/home/msfadmi n/secretDirectory/P asswords.txt After I cat the \$ cat /home/msfadmin/secretDirectory/passwords.txt passwords.txt file I was met with the Password01 following: Password01

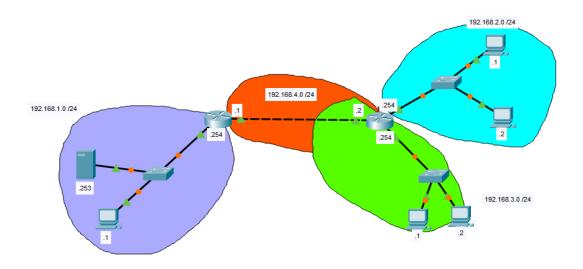

I have successfully performed a penetration test on our remote host machine using Armitage, I scanned for open ports, ran a Hail Mary and searched the directories for any hidden information, upon doing this I managed to find a secret directory with a text file containing passwords stored in plaintext.

The passwords are as follows:

Password01

4BlindMice

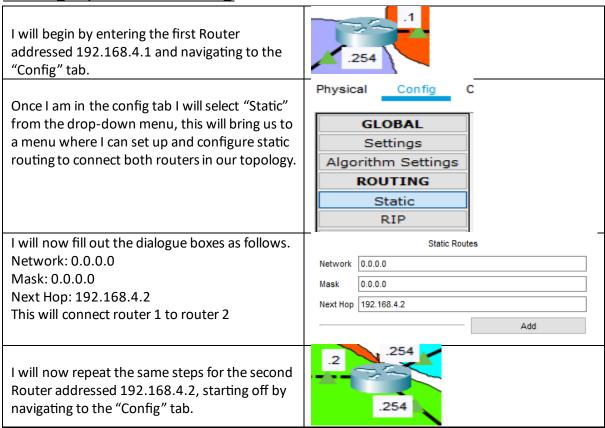

4BlindMice

Access Control Lists

In this segment using this topology that I have set up I will be configuring static routing between both Routers (4.1 and 4.2), I will then be creating an access list in order to deny access to the Web server and ICMP from the 192.168.3.0 network and allowing access from everywhere else.

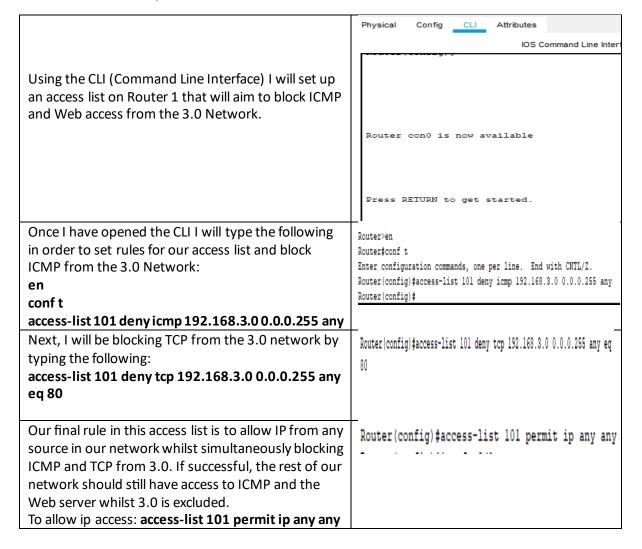

Setting Up Static Routing

Physical Config Once I have located the config tab I will once GLOBAL again select the static option so that I can begin setting up static routing on our second Router. Settings Algorithm Settings ROUTING Static RIP Static Routes I will once again fill out the dialogue boxes as Network 0.0.0.0 follows: 0.0.0.0 Network: 0.0.0.0 Next Hop 192.168.4.1 Mask: 0.0.0.0 Next Hop: 192.168.4.1 Add This will connect Router 2 back to Router 1 and ensure that static routing is set up both ways

Setting up and Implementing Access lists

In this segment I will be setting up an access list on our router 1 interface in order to prevent our 3.0 network from sending ICMP and accessing the Web server (192.168.1.253) whilst allowing Web and ICMP access to the 1.0, 2.0 and 4.0 Networks.

	1
access-list 101 permit ip any any	
Now that I have established our rules our last step is to implement our access list into our network to do this I will type: Int fa 0/1 (I am entering the interface on our router where our access list will be set up)	Router(config-if) #ip access-group 101 in Router(config-if) #exit Router(config) #exit
Once in our interface I will type: ip access-group 101 in exit exit	
Our access list has been set up successfully and it is now time to test if it has been implemented correctly. If successful, our 192.168.3.0 network will be unable to access ICMP pings and our Web server whilst the rest of our server still has access due to the access list specifications/guidelines	192.168.3.0 /24

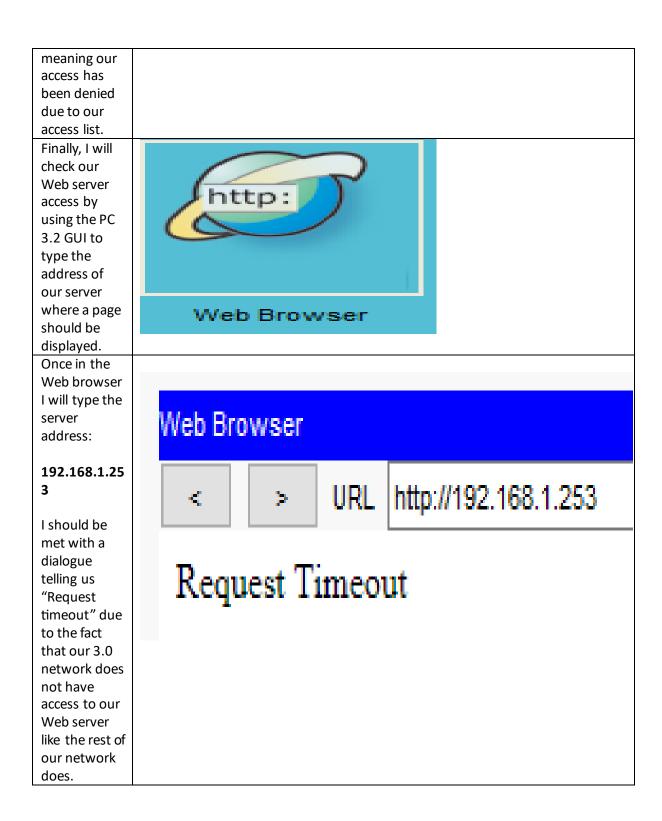

Testing our Access List

Now that I have set up our access list in the topology, I will test its effectiveness.

I will begin by checking if I can ping using ICMP on our 2.0 network that should have permissions I will also check if I can access the server's Web address.

I will test the 192.168.2.0 /24 2.0 network using PC 2.1 in order to ping our 1.253 server on the other side of our topology Packet Tracer PC Command Line 1.0 Once in the PC 2.1 I will C:\>ping 192.168.1.253 enter the terminal and Pinging 192.168.1.253 with 32 bytes of data: ping our server's Reply from 192.168.1.253: bytes=32 time<1ms TTL=126 address by Reply from 192.168.1.253: bytes=32 time=1ms TTL=126 typing: Reply from 192.168.1.253: bytes=32 time=9ms TTL=126 Reply from 192.168.1.253: bytes=32 time<1ms TTL=126 Ping 192.168.1.25 Ping statistics for 192.168.1.253: Packets: Sent = 4, Received = 4, Lost = 0 (0% loss), Approximate round trip times in milli-seconds: I have Minimum = 0ms, Maximum = 9ms, Average = 2ms obtained a reply telling us our ICMP ping was successful Next, I will test our Web server access http: by using the PC 2.1 GUI to type the address of our server Web Browser where a page should be displayed.

```
interface FastEthernet0/1
                        ip address 192.168.4.1 255.255.255.0
Finally, if I
                        ip access-group 101 in
enter the CLI
                        duplex auto
on Router 1
                        speed auto
and type sh
                       interface Vlanl
run I can
                        no ip address
show the run
                        shutdown
of the router
                       ip classless
through our
                       ip route 0.0.0.0 0.0.0.0 192.168.4.2
CLI.
                       ip flow-export version 9
Here if I
navigate to
                       access-list 101 deny icmp 192.168.3.0 0.0.0.255 any
our 0/1
                       access-list 101 deny tcp 192.168.3.0 0.0.0.255 any eq www
interface, I
                       access-list 101 permit ip any any
can see our
access list is
displayed and
                         -More-
each of its
specified
commands
alongside it.
```

This tells us that our access list has been set up and implemented successfully and that I have isolated our 3.0 network from the rest of our topology and limited its access to ICMP and the Web server.

Conclusion

In conclusion in this skills demo I successfully performed an audit on a remote host machine, I used NMAP to scan for any open ports and used online exploit databases to identify outdated software along with security concerns that may arise from them. I explained how they could pose a threat to the security of the machine and the server as a whole along with possible solutions in each scenario, I then used Armitage to run a penetration test on the remote host machine and exploited the outdated software in order to retrieve the contents of the passwords.txt file, I learned how important it is to keep software up to date in order to help prevent security risks. I then used the packet tracer file that I was provided to set up static routing between 2 routers along with an access control list that limits access to the web server and ICMP from the 192.168.3.0 network in the topology while allowing access from the other networks (1.0,2.0,4.0).
